## Overview

This document provides the details of an OVP Fast Processor Model variant.

OVP Fast Processor Models are written in C and provide a C API for use in C based platforms. The models also provide a native interface for use in SystemC TLM2 platforms.

The models are written using the OVP VMI API that provides a Virtual Machine Interface that defines the behavior of the processor. The VMI API makes a clear line between model and simulator allowing very good optimization and world class high speed performance. Most models are provided as a binary shared object and also as source. This allows the download and use of the model binary or the use of the source to explore and modify the model.

The models are run through an extensive QA and regression testing process and most model families are validated using technology provided by the processor IP owners. There is a companion document (OVP Guide to Using Processor Models) which explains the general concepts of OVP Fast Processor Models and their use. It is downloadable from the OVPworld website documentation pages.

### 1.1 Description

This model implements an ARM system containing clusters of MPCore processors communicating using a common GICv2 or GICv3 block.

By default, the system contains Cortex-A53MPx4 and Cortex-A57MPx4 clusters, but this can be changed using parameter “override\_clusterVariants”. This parameter is a comma-separated list of cluster components (e.g. “Cortex-A53MPx4,Cortex-A57MPx4”). Note that if a GICv2 is selected, the total number of PEs must not exceed 8.

### 1.2 Licensing

This document describes the interface to the MultiCluster only. Refer to documentation of individual clusters for information regarding implemented features, licensing and limitations.

## 1.3 Limitations

## 1.4 Features

By default, the model implements a GICv2. Parameter enableGICv3 can be used to select a GICv3 instead.
